## **Abstract**

This thesis demonstrates the design of RISC-V computer architecture that supports faster execution of motion planning algorithms for drone applications. First, it shows the analysis of computational performance of Rapidly-exploring Random Tree (RRT), a sampling-based motion planning algorithm commonly used in autonomous drones. Having identified collision detection as the biggest area of opportunity for improved performance, it describes the process of designing specialized hardware, taking advantage of parallelization, that quickly detects collisions. Finally, it presents how this specialized functional unit can be implemented in a processor, and the RISC-V Instruction Set Architecture (ISA) extended to invoke execution to massively reduce the execution time of collision detection.

## Introduction

### 1.1 Problem Summary

#### 1.1.1 Background

TODO: Summarize the following points:

- 1) Need for faster execution of motion planning in drones
- 2) Strategy of specialized hardware
- 3) RISC-V ISA and its potentials including extendibility

#### Robotics

For well over 2000 years, the concept of robotics, albeit not always with such a term, has fascinated humans. As early as the first century A.D., the Greek mathematician and engineer, Heron of Alexandria, described more than 100 different machines and automata in *Pneumatica* and *Automata*[1]. In 1898, Nikola Tesla demonstrated the first radio-controlled vessel. Since then, the world has seen widespread application of robotics in manufacturing, mining, transport, exploration, and weaponry. For the last few decades, robots have operated in controlled, largely unchanging environments (e.g. an assembly line) where their environment and movements are largely known *a priori*.

However, in recent years a new generation of autonomous robots has been developed for a wide range of real-world, complex applications. The increasing trend the use of autonomous robots is shown in Figure 1.1. These new robots, unlike those traditional ones described above, are required to adapt to the changing environment in which they operate. As such, they must perform motion planning in real time.

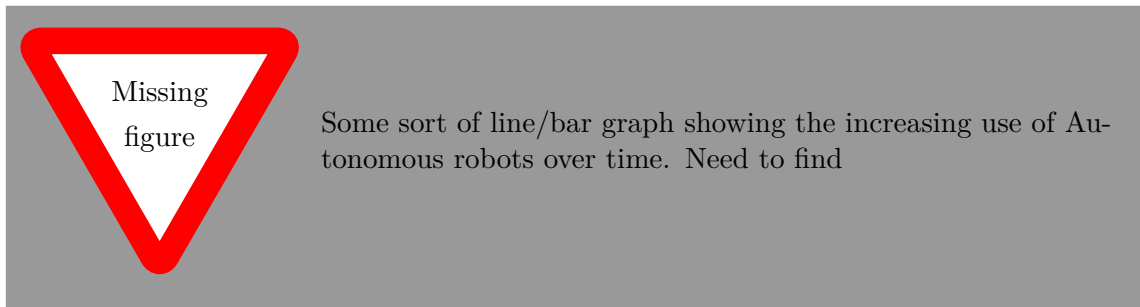

Figure 1.1: The use of Autonomous Robots over time

## Motion Planning

TODO: More of an introduction to motion planning.

Motion Planning refers to the problem of determining how a robot moves through a space to achieve a goal. Chapter 2 provides a detailed explanation of motion planning and of RRT, a commonly used motion planning algorithm.

On the algorithmic level, motion planning has been extensively studied and many solutions exist. However, current algorithms running on regular Central Processing Unit (CPU)s are too slow to execute in real time for robots operating in complex environments. Simply solving this problem with more raw computing power, using energy hungry Graphics Processing Unit (GPU)s may have merit in tethered robots. On the other hand, untethered applications, such as autonomous drones, where limiting power consumption is a primary concern, this strategy is infeasible.

## Hardware Acceleration

Specialized hardware designed to perform specific functions can yield significantly higher performance than software running on general purpose processors, and lower power consumption than GPUs.

More detail here. Reference prior work

## RISC-V

TODO: Introduction to RISC-V and its merits in this problem

### 1.1.2 Problem Definition

#### Problem Statement

Revise problem statement

Current processors cannot compute motion planning algorithms quickly enough for robots to operate in high complexity environments. Autonomous drones are a specific case of robots requiring real-time motion planning in complex environments. The state-of-the-art strategy of using a Graphics Processing Unit (GPU) to accelerate the execution of these algorithms requires too much power to be cost-effective or feasible for drones to sustain flight for useful periods of time.

#### End User

TODO: End User

## 1.2 Prior Work

Project Structure/Timeline

## Chapter 2

# Motion Planning in Software

### 2.1 Background

Motion Planning Algorithms refer to the set of algorithms that find possible sequences of valid configurations for a robot in a space.

TODO: Background on Motion Planning Algorithms.

### 2.2 Rapidly-Exploring Random Tree

#### 2.2.1 Algorithm

RRT is an algorithm designed to efficiently search, and thus plan a path through, a high-complexity environment by randomly sampling points and building a tree. The algorithm randomly samples points, draws an edge from the nearest currently existing node in the tree, to grow the tree in the space. It is inherently biased to grow towards large unsearched areas of the problem. RRT was developed by S. LaVelle [2] and J. Kuffner [3]. It is used in autonomous robotic motion planning problems such as autonomous drones, the focus of this thesis.

The RRT Algorithm with Collision Detection can be seen in Algorithm 2.1.

---

**Algorithm 2.1:** Rapidly-exploring Random Tree with Collision Detection
 

---

**Inputs:** Space  $S$  with obstacles  
**Output:** Collision free graph  $G$  with  $K$  nodes & edges  
 $G.init()$ ;  
**for**  $k = 1$  to  $K$  **do**  
  **while**  $\neg \text{pointCollision}(node_{new})$  **do**  
     $q_{rand} \leftarrow \text{getRandomNode}()$ ;  
     $q_{near} \leftarrow \text{findNearestNode}()$ ;  
     $q_{new} \leftarrow \text{stepFromTo}()$ ;  
  **end**  
   $e_{new} \leftarrow \text{newEdge}(q_{near}, q_{new})$   
  **if**  $\neg \text{edgeCollision}(e_{new})$  **then**  
     $G.addNode(q_{new})$ ;  
     $G.addEdge(e_{new})$ ;  
  **else**  
     $k = k - 1$ ;  
  **end**  
**end**

---

Relook at above algorithm

### 2.2.2 Implementation

The project required an implementation of RRT that fulfilled the following criteria:

1. Implemented in C
2. Modelled a drone as a point in a 3D space
3. Was implemented in such a way that made it suitable for CPU execution analysis.

The original intention was to find an existing implementation of RRT that could fulfill these requirements. Most open source implementations found online were in Python, and all those implemented in C were unsuitable[4][5][6][7], as they had extraneous GUIs, reliance on external Application Programming Interface (API)s, and other features that would distort analysis of algorithmic hotspots.

As a result, it was necessary to build a C implementation of RRT from the ground up. It can be found in this project's GitHub repository. It follows Algorithm 2.1 closely. For monitoring correctness, I build in an optional GUI that shows the tree, starting node, and obstacles.

## Implementation in 2D

The first step was to implement RRT with a 2-Dimensional workspace.

[More detail](#)

Figure 2.1: 2D RRT Implementation shown by GUI

### Implementation in 3D

Describe implementation in 3D

Figure 2.2: 3D RRT Implementation shown by GUI

#### 2.2.3 Performance Analysis

To restate, the aim of this thesis is to design a computer processor with reduced execution time of motion planning algorithms, such as RRT. As such, it is important to understand the elements of the algorithm that have the highest percentage of CPU execution time. To determine this, it was necessary to implement my own, naive but typical, RRT in C. This program could then be compiled and analysed using a software performance profiling tool. With this, I could design experiments to determine the critical RRT functions (those occupying a majority of CPU time) and see how this varies given different parameters.

Introduction to purpose of analysis and methods of doing so. Something better than the above

### VTune Amplifier Analysis

VTune Amplifier performance profiler is an application for software performance analysis. It provides functionality to examine hotspots for CPU execution time through a top down analysis, shown below in Figure 2.3. As can be seen from the figure, the top down analysis tool shows the percentage of CPU time taken up by each function. I used this tool to profile the algorithm's performance as I changed certain parameters.

Rewrite the above
